The specific learning objectives are that students graduating from 16.20 will be able to:

- use the one-dimensional and two-dimensional structural idealizations of beams, columns, rods, and shell beams to determine stress and deformation states.
- apply such structural idealizations to model general structural configurations

- Correction Solution: 1. In Figure 2, from the Pythagore theorem we have:  $\sigma_1^2 + \sigma_2^2 = R^2$  and  $\sigma_1 = \sigma_2$  hence:  $\sigma_1^2 + \sigma_1^2 = R^2$  finally we obtain the following relation for the radius of the circle:  $R = \frac{1}{\sqrt{2}} (\sigma_{11} + \sigma_{22})$ . The value of principal stresses is equal to the ordinate of the origin  $(\frac{1}{2} (\sigma_{11} + \sigma_{22}))$

The deformation near a material particle of

the classical continuum is produced by successive superposition of a rigid-body translation, a pure stretch along principal directions of strain and a rigid-body rotation of those directions. The rotational part of deformation is particularly important in the non-linear analysis of thin-walled solid structures such as beams, thin-

It seems that the research concerning the application of finite rotations is carried out independently in different fields of structural mechanics.
