It all starts with developing the highest-performance engine for small rockets. Launcher E-2 engines are 3D printed in high-performance copper alloy and require less propellant to get to orbit - allowing Launcher to deliver more satellite cargo per rocket and as a result, offer a lower price than our competitors.

A rocket engine is generally throwing mass in the form of a high-pressure gas. The engine throws the mass of gas out in one direction in order to get a reaction in the opposite direction. The mass comes from the weight of the fuel that the rocket engine burns.

How Rocket Engines Work | HowStuffWorks

A rocket engine uses stored rocket propellants as the reaction mass for forming a high-speed propulsive jet of fluid, usually high-temperature gas. Rocket engines are reaction engines, producing thrust by ejecting mass rearward, in accordance with Newton's third law.

Rocket engines operate by expelling a high-temperature gas through a nozzle to produce thrust. This thrust acts to accelerate a spacecraft in the direction opposite to that of the expelled gas through the application of Isaac Newton's third law of motion: "For every action, there is an equal and opposite reaction."

Go build a rocket as long as you know where you're going, and use plenty of plywood and other stuff you know when that's what works. Whatever you build, it will explode, so blow it up yourself first, and document what happened so you can learn from those explosions.
