In 3D computer graphics, polygonal modeling is an approach for modeling objects by representing or approximating their surfaces using polygon meshes. Polygonal modeling is well suited to scanline rendering and is therefore the method of choice for real-time computer graphics. Alternate methods of representing 3D objects include NURBS surfaces, subdivision surfaces, and equation-based ...

What is polygonal modeling? Polygonal modeling - low-level modeling, which allows you to visualize an object using a polygon mesh. Polygonal meshes consist of such subobjects: • The vertex is the junction point of the edges, there can be as many as desired; • Edges - lines that protrude by the boundaries of faces; • Faces or polygons - grid cells, sections of the plane, which are most often triangular or quadrangular. A polygonal mesh can consist of a huge number of identical cells.

Polygonal modeling is the creation of a polygon mesh that repeats the shapes of the desired objects. This is the very first kind of three-dimensional modeling. Polygonal modeling saves computer resources; therefore, models created by such methods are more often used for 3D visualization and in games.

When many faces are connected together they create a network of faces called a polygon mesh (also referred to as a polyset or a polygonal object). You create your 3D polygonal models using polygon meshes. Polygon meshes can be created using a variety of techniques. For more information on these techniques see Polygon modeling overview.

The model, named after Edgar Gilbert, allows cracks to form starting from randomly scattered over the plane; each crack propagates in two opposite directions along a line through the initiation point, its slope chosen at random, creating a tessellation of irregular convex polygons.

Polygonal models, their representations, and renditions have been studied extensively since the beginnings of computer graphics (see, for example, Foley et al., 1990). The classification of edges of a polygon mesh into contour, sharp, smooth, and triangulation edges was first suggested by Raab (1998); see also Schlechtweg and Raab (1998). For several years, it was considered a difficult open problem to render a geometric model with only a small number of lines; Raab was the first to provide ...

The main difference between polygonal and NURBS modeling is the way the mesh is calculated by the computer. For polygon modeling it calculates polygons, which are flat planes that comprise a 3D shape (the way that a cube is made out of 6 squares for example). NURBS calculates the mesh as splines between points, which can make curves out of a single section of geometry.

Providing in-depth coverage of polygonal modeling, this book is dedicated to a discussion of the technical aspects and methods of modeling organic and inorganic objects, revealing the tricks for absolute control of polygonal mesh modeling. The book includes an illustrated quick start modeling guide to 3dsmax and Maya.

One question we get regularly at TransMagic is "Can I convert polygonal models to CAD models?". Well now the answer is yes; as of release 12, TransMagic Expert has the capability to convert polygonal formats to geometric CAD formats. I asked TransMagic's head of development, Craig Dennis, about this process, as well as some of the benefits and challenges of the Poly to CAD process:

Manufacture from Polygonal Models In reverse-engineering, the first step of the workflow is known as meshing, the process of transforming digitized point clouds into a polygonal model. During this process, state-of-the-art data-processing techniques can be applied to the point cloud, such as curvature-based sampling and point smoothing.
